FOREST FIRE BURNING CONDITIONS
IN THE LAKE STATES

By John S. Crosby, Forester

INTRODUCTION

Both the occurrence and the behavior of forest fires differ as the severity of burning conditions change. So, to provide adequate protection at reasonable cost, efficient fire-protection agencies vary the intensity of organization. This is largely a matter of judgment. However, a guide to the intensity of organization required is provided by the Lake States Burning Index Meter, which has been in use since 1936 by the forest protection organizations in Michigan, Wisconsin, and Minnesota.

To learn more about fire occurrence and behavior under different burning conditions, 12 years' records from the eight national forest units of the Lake States were summarized. These records covered the period 1936 through 1947, during which the burning index meter was used. The results show the normal frequency and distribution of days in the various classes of burning conditions throughout the fire season, and the relative danger prevailing under different burning conditions.

WHAT THE BURNING INDEX METER IS

Since the study is based chiefly on readings of the burning index meter, a very brief description of it is desirable. The Lake States Burning Index Meter resulted from research designed to provide a measure of the severity of burning conditions. It is based upon the fact that the inflammability of fuels is in proportion to their moisture content. Meter values, in turn, are derived from the weather factors which influence fuel moisture, and which have been correlated with fuel moisture to give an index of burning conditions. The weather factors measured are amount of rainfall, number of days since last rain, relative humidity, and wind velocity.

The scale of the meter is calibrated 0 to 100. Zero represents poorest burning conditions, while 100 represents extreme burning conditions. The scale is divided into seven classes of burning conditions. These are: 0-1, safe; 2-3, very low; 4-6, low; 7-12, moderate; 13-24, high; 25-49, very high; and 50-100, extreme.

1/ Maintained at University Farm, St. Paul, Minnesota, in cooperation with the University of Minnesota.

Nearly every state protection district and national forest ranger district maintains at least one fire weather station where observations are normally made daily at 8:00 a.m., noon, and 5:00 p.m. during the fire season. Burning-index ratings are computed from these observations, and are assumed to be representative of the district.

HOW THE STUDY WAS MADE

The data used consists of burning index meter readings and records of number and size of fires for the same localities and periods. To obtain comparable values for different forests and years, certain arbitrary decisions had to be made as to season covered and method of classifying days.

Season Covered

The fire season in the Lake States varies in length and severity because of differences in the weather. In general it corresponds with the snow-free period, usually beginning in March and ending in November.

Fire weather reports and meter readings are required by the Forest Service from April 1 through October 31, though they are started earlier or continued later as snow conditions dictate. However, as comparable data are available only for the period April through October, March and November data were not included in the present analysis.

Method of Classifying Days

In this summary of national forest records, a burning-index rating for each forest was given to each day of the fire season corresponding to the maximum rating recorded at any of the several stations on the forest. The term "forest day" is used to identify this unit of time and area. In summarizing the data, each daily forest maximum meter reading from 0 to 100 was placed in the appropriate one of the seven groups, (0-1, 2-3, 4-6, 7-2, etc.) and all fires starting on a forest were classified according to the rating of the "forest day."

RESULTS

Frequency of Days in Each Burning Index Class by Years and Months

Since many decisions in regard to fire control are now based upon the burning-index class of day, it is important to know how many days normally fall in the different classes each month and year, and also the variation from normal (Tables 1 and 2, Charts 1 and 2).^{2/} As might be expected, there is considerable variation from month to month, year to year, and forest to forest. However, the 12-year averages for the period 1936-1947 appear quite stable, covering a good range of dry and wet seasons, and should, therefore, provide a reasonably accurate group of values.

^{2/} Annual figures for each forest are given in the appendix.

NUMBER OF DAYS IN EACH BURNING INDEX CLASS

Average of eight Lake States National Forests for a 12 year period (1936-1947), and range of variation between years.

Average of eight Lake States National Forests for a 12 year period (1936-1947), and range of variation between the 12-year averages for each individual National Forest.

^{1/} To nearest whole day.
^{2/} Less than 0.5 day.

Relative Severity

To simplify the comparison of areas or periods, a single figure, the relative severity,^{3/} has been used. This figure is essentially the percent of worst possible conditions, assuming that worst possible conditions would be met if all days were extreme.

On a 12-year basis the ratings provide a measure of the difference in burning conditions prevailing between months, and between forests, and a somewhat less important appraisal of yearly variation. (Tables 3, 4, and 5).

Evaluation of Burning Index Classes

To know the normal frequency and distribution of burning conditions is important only if there is knowledge of what a given burning-index class means in terms of fire occurrence and size. Burning conditions are determined by the weather, but fire danger depends upon several other factors. The more important of these are: risk, or the chance of fires being started, and hazard, or the character of the fuels.

^{3/} Obtained by weighting the number of days in each class and dividing the sum of the weighted values by the total number of days, times the weight given to the extreme class. Weights used are 1, 2, 4, 8, 16, 32, and 64 respectively per class.

1941	12.9	1947	17.1

12-year average = 14.7

^{1/} See footnote 3 on previous page.

This complexity of factors contributing to number and size of fires makes impossible the accurate forecasting of fire-control requirements at the local level for a specific time. The trends produced over the 12-years, while an integration of all the factors, nevertheless indicate only the relative danger prevailing at the different burning-index levels. However, frequency and size of fires, together give a fairly reliable measure of the danger.

Frequency of Occurrence

Frequency of occurrence is a partial measure of risk of fires starting, and hence a factor in the evaluation of the various severity classes. Fire occurrence is shown in three ways: (1) number of fires per day by classes of days; (2) percent of days on which fires occurred (percent of fire days); and (3) number of fires per fire day. Upon all three bases 12-year averages of all forests show that occurrence increases with higher burning index (Table 6, and Charts 3a, 3b, and 3c).

Size of Fires

The size of the average fire in each class is also a factor in evaluating the danger associated with the various degrees of severity of burning conditions. As burning conditions become more severe, fires give off more heat, burn deeper, and spread faster. They are, therefore, more difficult to control, and according to these data, are of larger size. (Table 6, Chart 3d).

The 12-year records from the 8 national forest units in the Lake States show that the size of the average fire in each of the seven classes is approximately doubled in the next more severe class.

Influence of Large Fires

During the 12 years studied, 1.5 percent of the 4,909 fires that occurred were 100 acres or larger in size, and accounted for three-fourths of the total area burned. These fires alone raise the average area burned per fire of all fires from 4.3 acres to 17.8 acres per fire. While these figures are somewhat startling, it is not unusual for the record of well-established fire-protection organizations to show that most fires are held to small size, while infrequent fires become large for one reason or another.

An analysis was made of large fires (100 acres or more) which could be clearly classified as to burning conditions at start of the fire as taken at the station nearest to the fire. This illustrated the tendency toward more and larger fires as burning conditions became more severe. (Table 7).

None of these fires occurred on days classified "safe" or "very low," and only one fire occurred on a "low" day. The highest frequency of the remainder fell on "very high" days. The average size of large fires also increases from "low" to "extreme" days. Thus, while large fires have occurred on all classes of days from "low" to "extreme," there is a marked increase in the size of fires on the more severe days.

Total	122	2,954	9,268	13,180	19,249	44,773
Size of average fire larger than 100 acres	122	197	545	599	1,604	668

1/ No fires of 100 acres or more occurred on Safe (0-1) or Very low (2-3) days.

DISCUSSION

The data presented provide a region-wide evaluation of the average fire danger prevailing at given burning index levels based on number of fires and area burned on the national forest of the Lake States. The relative danger indicated for each burning index class, however, is more significant locally than the specific values given due to differences between forests in risk, hazard, and to some extent climate. For example, while one forest may have twice as many fires as another at any given burning index level, the average number of fires per day will approximately double with each increase in burning index class.

Since the data presented are forest averages, the numbers of fires indicated is higher than could normally be expected on any single ranger district, due to the smaller area of the ranger district. However, the relative difference between dangers prevailing at different burning index levels should remain the same regardless of size of the protection unit.

On similar areas outside the national forests the distribution of days in the various severity classes of burning conditions should apply equally well, though numbers and size of fires may vary considerably due to variation in policies, risk, and prevailing hazards.

SUMMARY

Results of the analysis^{4/} of forest fire records of the national forests of the Lake States for the period 1936 through 1947 show that as burning conditions become more severe, fire danger likewise becomes more severe. Thus:

1. The number of fires per day is approximately doubled with each increase to a more severe class of day.
2. The size of an average fire is approximately doubled for each increase of burning conditions to a more severe class of day.

No fire of 100 acres or more occurred when the burning index was "safe" or "very low." One large fire out of 67 occurred on a "low" day, while all the others occurred on moderate or more severe days, and as the burning conditions became more severe these fires were found to be larger.

4/ Table 6 summarizes the results of the analysis.

* * * * *

APPENDIX

The following tables give specific data for each national forest. Separate tables are given for the Manistee and Huron units of the lower Michigan National Forest, since the records were started separately before the two units were consolidated.

EVALUATION OF BURNING INDEX CLASSES
